Habibie, Kompleks Puspipstek Gedung 460, Kec. Setu, Serpong, Tangerang Selatan, 15314, Indonesia	<p>"Smart nanocomposite packaging film derived from Indonesian Indigenous bioresources incorporated with green synthesized nano-silica for tropical fish freshness monitoring".</p> <p>The synergetic contribution of nanotechnology and bioactive compounds appears to be a promising approach to designing a smart packaging film based on Indonesian indigenous bioresources. An innovative approach by incorporating green synthesized SiO₂ nanoparticles and bioactive compounds from sapan wood (<i>Caesalpinia L.</i>) extract in starch-based film emerges as a promising smart packaging for extending and monitoring the freshness of sliced tropical fish products. This concept is authentic and remains unexplored, signifying its novelty. The aim is to improve the functionality of the packaging films to make them intelligent and active, as well as enhance their physicochemical properties. The anticipated outcome revolves around sliced food products' shelf-life extension and quality monitoring. This study contributes to developing environmentally friendly food packaging while enhancing its smart features.</p>	Rp	50.000.000

Jogja-Wonosari km 31.5, Gading, Playen, Gunungkidul, Yogyakarta	Sorghum is notably abundant in polyphenols, such as phenolic acids, tannins, and flavonoids, which are primarily concentrated in the pericarp and testa of the grains. The impact of heating on the antioxidant properties, as well as the structure and quantity of these phenolic compounds, varies depending on the cooking method, duration, and temperature used. It is essential to analyze the phenolic content and its metabolite profile in foods exposed to various heating durations and temperatures to determine the optimal conditions for retaining the phenolic compounds in sorghum bran. This research is particularly focused on exploring the potential of red sorghum bran as a functional food ingredient and antioxidant additive, a topic that has not been extensively investigated. The hypothesis posits that optimal processing, including both heating and encapsulation, will preserve the phenolic compounds and metabolites in sorghum bran.	Rp 49.966.500

Prof. Soedarto, Tembalang	The program B30 was developed by government since January 1, 2020. Currently, the government actively has plan to develop a proposed nomenclature for biodiesel B40, B50, even B100. Thus, the biodiesel production from waste cooking oil is an innovative approach to encourage government higher than B30 fuel program. Commonly, fatty acid methyl esters (FAME) are commonly referred to as biodiesel. FAME produced from waste cooking oil has purity 70-80% contained by-products of glycerol 20-30% from transesterification reaction. The impurities in the FAME must completely removed from biodiesel due to lead to engine operation problems. Further, the presence of glycerol and water in biodiesel may lowering the quality of the biodiesel B100. The conventional process of biodiesel purification is vacuum distillation but it needs wide energy consumption. Membrane separation technology is one of the innovative technologies to remove free glycerol from biodiesel in order to meet the ASTM D6751 and EN 14214 standards. According to the standard SNI 7182:2015, the purity of biodiesel production is required 96.5%. Therefore, to reach high purity of refining biodiesel, the proposed research will study polyethersulfone bio-based tannin acid which has superior antifouling and antibacterial. PEG will add to membrane for improve the pore structure to enhance high purity of biodiesel. Thus, it is expected to high purity biodiesel which as an environmentally friendly fuel.	Rp	49.125.000
